Educational Leadership and Policy Analysis

Abstract

Data-driven instructional improvement relies on developing coherent systems that allow school staff to generate, interpret and act upon quality formative information on students and school programs. This paper offers a formative feedback system model that captures how school leaders and teachers structure artifacts and practices to create formative information flows across interventions, assessments and actuation spaces. A formative feedback system model describes the organizational capacity upon which innovations such as comprehensive school reforms, benchmark assessment systems and student behavior management systems draw to improve teaching and learning in schools.

Submitted for publication to the *Peabody Journal of Education*
February 2009

This paper presents the concept of a formative feedback system to identify the capacity that many schools are developing in the quest to meet the demands of high-stakes accountability policies. The press for raising student test scores has led many schools to reframe school instruction and information systems (Yeh, 2005; Honey, et. al. 2005; Wayman, 2005; Sharkey & Murnane, 2006). However, as Richard Elmore (2000) predicted, accountability-based reforms have called on schools to move beyond information system design to develop new kinds of capacity for instructional improvement. Since school staff cannot rely on standardized test results to directly inform changes in their classroom-level practices, schools must also engage in instructional system redesign - first to link everyday classroom practices with school-wide outcomes, and second to develop data-driven practices that give teachers local, on-going information to benchmark student learning progress.

Our recent research into how schools develop the capacity to use data to effectively to improve student learning has shown us how local actors develop data-driven instructional systems to improve classroom practice (Halverson, et. al., 2007; Halverson & Thomas, 2007). One key feature of this research has been to identify the operation of *formative feedback systems*. Formative feedback systems are networks of structures, people, and practices that help teachers and administrators translate testing data into practical information for everyday use. Without accurate and timely formative feedback on the results of intended interventions, school leaders and teacher fly blind in their efforts to link what they expect to what actually happens in classrooms. Building these functions into the everyday school instructional program has proven to be a daunting,

resource intensive challenge for school leaders. However, once assembled and implemented, formative feedback systems can provide accurate, incremental and actionable measures of student learning and behavior directly linked to the units of practice most meaningful to classroom teaching and learning.

In this paper, I argue that the formative feedback systems constitute the socio-technical processes that leaders and teachers coordinate to develop the capacity to make sense of assessment data. I then describe the generic capacities that local school leaders can and do develop to meet the information demands required by high-stakes accountability reforms. In other words, formative feedback systems name the local design work required to create the school capacity for meeting the demands of accountability policies. Our discussion uses some of the core ideas from the organizational change and information feedback literature to describe how these formative feedback practices operate and have emerged in the schools we studied.

The paper focuses on case studies of three schools in order to illustrate a range of formative feedback systems in action. The case study analyses will show how interventions can range from comprehensive school reforms, to reading initiative and student behavior recording systems; how assessments range from commercial products to locally developed benchmark assessment tools; and how teachers make sense of and act upon information in the context of daily teaching and learning. After identifying the key functions involved in a formative feedback system, we then analyze the intersection between the functions in order to explain where similar educational innovations fit into the family of formative feedback systems, and to show how the characteristics of

formative feedback systems can illustrate the conditions for successful implementation of benchmark assessments.

Formative Feedback Systems

Formative feedback systems draw on a rich body of research on learning and organizational theory. From a systems perspective, a school is a complex, messy information system that issues many conflicting performance signals (Wallace & Pocklington, 2002). Systems theory language helps to describe the organizational capacity to generate, interpret and use feedback. Originally developed in cybernetics and engineering research (von Bertalanffy, 1969), feedback became a popular term in systems theory research (Senge, 1994; Richardson, 1991; Greve, 2003). Feedback is system-generated information generated that is looped back to control system processes. In its simplest form, a feedback system consists of four main parts: signals, sensors, signal processors, and controllers (von Bertalanffy, 1969; Richardson, 1991). Signals contain information from within or outside of the system. Sensors detect the presence of the signals and processors establish the significance of the signal. Signal processors analyze and interpret the signal meaning, and controllers determine the action to be taken as a result, which may result in a new signal that acts as new input into the information system.

Formative feedback research in education has traditionally focused on the classroom. Black and Wiliam's (1998) work summarizes research on the critical role that formative feedback plays at the three levels of teacher, student, and teacher-student interaction. Formative feedback is information that can be used to guide both the teaching and learning process. At the teacher level, teachers need accurate information

about the specific processes and outcomes of student learning to effectively shape teaching. Students also need accurate self-assessments to guide their learning processes.

The formative feedback process comes to life through student-teacher and student-student interaction in the form of questions that highlight learning gaps and through discussions that show how these gaps might be addressed. Black and Wiliam's summary of prior research on formative feedback demonstrates impressive learning gains within the classroom. The policy dimension of formative feedback is to ensure that schools are able to tap into rich, generative bodies of formative information on the learning process and to make sure that the information is actually used by teachers and students to guide learning. A formative feedback system extends the insights from the classroom to the school as a learning organization. Extending Black & Wiliam's (1998) three-level description of a classroom-based system to the school means that teachers and school leaders would need accurate information on instructional program success, teachers themselves would need accurate information on their own efforts to teach the instructional program, and legitimate opportunities would need to be provided for interaction to raise questions and discuss solutions. A formative feedback system model that would generate useful information about teaching and learning in schools would a) generate information signals that measure how students performed in terms of an *intervention*, b) provide sensor and processor functions to *assess* information signals, and c) controllers that could *actuate* this new knowledge in order to adjust the instructional process. The three functions of *intervention*, *assessment* and *actuation* comprise the core components of a formative feedback system model. (Figure 1)

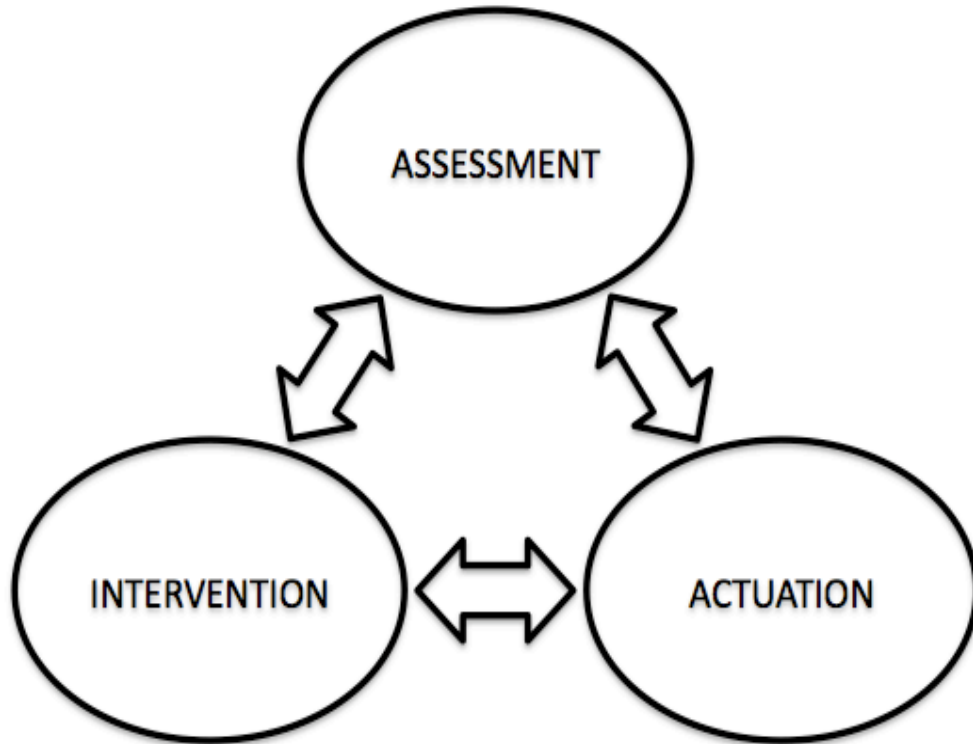

Figure 1: Formative Feedback System Model

Interventions. Interventions describe the programs and policies that leaders and teachers use to guide student learning. At the group level, intervention artifacts can take the form of curricular materials, such as textbooks, experiments, worksheets, computer programs, etc., that teachers used to structure classroom learning. At the individual level, a program such as the special education individualized education program (IEP) is an example of an intervention that customizes instructional and behavioral resources to meet the perceived needs of certain students in and out of the classroom. Taken together, these interventions comprise the instructional program that the school staff uses to influence student learning. The learning that results from an interventions is analogous to the *signal* in classic information processing systems theory.

Assessments. Assessments pick up the information signal generated by the interventions. Assessments play the *sensor* role in the formative feedback system. Assessments provide the information to help teachers determine the degree to which signal received (estimates of student learning) correspond with the learning goals built into the interventions. Assessments provide specific information about the degree to which aspects of the intervention succeeded or failed to result in student learning. The match between the assessment and the intervention is critical – if the information generated by the intervention differs from the signal detected by the assessment, then the system will need a “translation” capacity in order to make sense of what the intervention results mean.

Actuation. Assessments of interventions, however well designed, merely provide information. Schools need structured occasions to turn assessment information into actionable knowledge. Actuation refers the process through which faculty and staff come to understand, and act upon, the effects of their interventions on student learning. Designing for actuation means setting up legitimate spaces, such as faculty, grade and team level meetings, for teachers to reflect upon the data and to make decisions about how to alter program delivery for students, or, in cases of significant problems revealed by the assessment, how to alter the interventions or the assessments themselves. Actuation spaces reflect the *signal processing* and the *controller aspects* of the classical feedback systems model. Actuation spaces provide legitimate occasions for practitioners to make sense of assessment information, and, with adequate organizational support, provide the opportunity for staff to make appropriate adjustments to the intervention.

Methods

Our study of *data-driven instructional systems* (DDIS) (Halverson, et. al., 2007) investigated how school leaders and teachers are engaged in using data to redesign their local instructional and assessment practices. This paper represents data collected during a five-year National Science Foundation-funded research project designed to study how leaders create social and technical systems to help teachers use achievement data in their instruction. In several of our schools, we found closed information sub-systems that both generated information on student learning and program performance, and provided legitimate contexts for faculty and staff to make sense of and act upon information. From this larger sample, we identified four schools that illustrate the design and operation of formative feedback systems (Table 1). This section will review the methods we developed to conduct the DDIS research in general, and to describe the sites and artifacts we will highlight in the findings and analysis sections that follow.

Table 1: Formative Feedback System DDIS Schools

School	Grades	Location	Size (Students)	Free/Reduced Lunch	Formative Feedback System	Principal Tenure
Pearson	K-6	Small Town	300	60%	Balanced Literacy	8 yrs
Walker	3-5	Rural	400	5%	MAP	9 yrs
Malcolm	K-6	Urban	220	68%	Student Behavior	6 yrs
Harrison	K-8	Urban	800	70%	Direct Instruction	4 yrs

Data collection. The study design documented data-driven leadership and instructional practices in order to describe the similarities and differences among schools’

instantiations of the DDIS. In order to identify schools successful in using data to improve learning, we consulted with educational leaders at the university, state, and district levels in order to generate a list of elementary and middle schools known for improving test scores and with leaders who were known for using data well with their teachers. From our initial list, we narrowed our sites to nine rural, urban and suburban schools recognized for strong data-driven decision-making and records of improving student achievement. We gave highest priority to schools with the strongest record of improving student achievement. In order to document and describe the school-level DDIS we collected a variety of data, including 107 structured interviews with school teachers and leaders; 135 1-3 hr. observations of classroom teaching sessions, faculty meetings, professional development sessions, data retreats, and other important events as identified by the staff; and the collection of any documents that appeared relevant to data-driven practices, such as school improvement plans, staffing charts, budgetary information and parent/community handouts.

Data analysis. The study approach to data analysis was a two-step, iterative process: (1) Intrinsic case development (Stake, 2000) to construct an initial theory of data-driven decision making — the DDIS framework — based on prior research on how schools meet the demands of external accountability and (2) Instrumental case development (Stake, 2000) to understand how this generic model works in individual schools. Our analysis draws on a data set composed of individual school case studies. Relying on organizational and school change literature, we developed a DDIS framework that described six central functions for how successful schools use data to inform instruction (for a more detailed elaboration of the DDIS framework, see Halverson,

Grigg, Prichett & Thomas, 2007). These functions helped to describe how data enter the school, how data are stored, how practitioners use data to set goals and develop plans, what schools put into place as a result of the data, and how students are prepared to generate the next round of achievement data.

After constructing this initial model from across all of our case studies, we focused on the evidence of systemic formative feedback use to guide the coding of data within each individual school. We developed an iterative approach to a coding process (Strauss & Corbin, 2006) to sort our data into the DDIS categories and identified the key artifacts leaders and teachers used to address DDIS functions. We then reanalyzed the field notes, interviews, and documents to give us deeper insight into the individual schools' approaches to the DDIS. In this paper, we will focus on the data that emerged as relevant to understanding the schools' formative feedback systems.

Formative Feedback Systems

We observed a variety of formative feedback practices throughout the classroom and professional interactions in our schools. Much of the feedback we observed involved comments targeted toward individual students and concerned the direction or correction of student classroom work. Student-targeted feedback was communicated directly toward students; other feedback was shared among staff with the purpose of eventually influencing student learning. Feedback information seemed to occur as a natural outgrowth of teaching and learning, but a formative feedback system was something designed and maintained by school leaders. While teachers generated and shared much of the information used as formative feedback, leaders took responsibility for establishing legitimate occasions (e.g. faculty meetings, role redefinitions, classroom assignments)

that coordinated the flow of formative information. School leaders structured formative feedback systems as intentional efforts to coordinate information flow about performance quality across the instructional, assessment and professional interactions spaces. Thus, while we observed a variety of formative feedback in the schools we studied, we found relatively few formative feedback systems intentionally designed to elicit and use information to improve the instructional program as whole.

Picking out the specific functions from the tangled network of instructional and assessment practices in each school proved to be an ambiguous and messy task. Most school instructional practices evolve to satisfy multiple instructional, social and personal functions. Simple interventions, such as scheduling changes or afterschool programs, over time acquire new uses or become obstacles for new changes as they integrate with the organic development of a school culture. Artificially isolating information functions from the rich network of school practices runs the risk of misrepresenting the degree to which the identified practices were intentionally designed to serve the functions we highlight. However, the information functions we identified did not appear to simply spring into life spontaneously from the vibrant stew of school culture. We found evidence of the intentional design of each of these information functions, and evidence that leaders and teachers intentionally coordinated these functions to provide formative feedback on central aspects of the school instructional program. These findings should not be taken as clean, abstract models for replication as best practices, but rather as examples of how leaders and teachers can create new forms of knowledge exchange in the midst of the exigencies of real school cultures.

In the next section, we will analyze aspects of the formative feedback systems we found in four of the DDIS schools in terms of the intervention – assessment – actuation model. Each of the formative feedback systems was designed to elicit information about a specific aspect of the instructional program; and each involved the dedication of significant human and material resources to maintain a formative information flow. Although each of the schools in the study addressed all three components of the formative feedback model, two of the schools (Harrison and Pearson) are chosen to highlight the role of the intervention, one (Walker) to highlight assessment, and the Malcolm school case to highlight the role of the actuation space. The analysis will illustrate the functions of formative feedback system components and how leaders and teachers designed features and linkages to ensure formative information flow.

Interventions

The term intervention names the program or activities schools use to organize the school instructional program. Schools use a great variety of interventions to guide student learning, including curricula, student behavior programs, special education and guidance activities, and extra-curricular activities. Each of these interventions provides structured or sequenced activities designed to influence student learning in some intended way. Halverson (2007) categorized interventions in terms of the *artifacts* that school staff use to influence student learning. Most of the interventions used for instruction in schools are received artifacts, that is, they originate from outside the school community. These artifacts included textbook and curriculum packages or computer systems. Districts often play a key role in selecting and distributing received intervention artifacts to schools. Locally designed artifacts include interventions such as teacher-assembled lessons,

individualized education programs, and many after-school activities. Taken together, the aggregation of received and locally-designed artifacts comprises the school instructional program, a network of programs and policies that evolve over time as teachers and leaders add lessons, texts and activities to their classroom instructional practices (Halverson, 2003). In the following sections, we highlight two cases of instructional interventions – the Harrison comprehensive school reform and the Pearson locally-designed literacy program – to illustrate a range of how schools assemble programs and policies into an instructional intervention that generates an actionable feedback signal.

Harrison's Direct Instruction Program. A formative feedback system depends upon the effort made by local school leaders and teachers to build an intervention that generates a coherent *signal* about the degree to which the instructional program improves student learning. The comprehensive school reform program Direct Instruction played a central role in Harrison School's formative feedback system. Direct Instruction (DI) is a comprehensive school reform (CSR) model that focuses on a tightly structured curriculum and assessment sequence. DI consists of a series of scripted lessons and orchestrated classroom interactions that provide both teachers and students with clear, prompt feedback on student learning. DI is one of a small number of CSR programs found to have significant positive effects on student learning across implementations (Borman, Hewes, Overman and Brown, 2003). Despite its predictable effects on student learning, DI has proven a controversial curriculum that breaks learning goals into smaller, scripted chunks that reduce teacher autonomy and decontextualize student literacy skills from actual literacy practice (See, for example, Commeyras, et. al., 2003; Kuhn, 2007). Our interest here is not to engage in the debate over the merits of DI, but to note how the

leaders and teachers at Harrison used DI to generate a reliable signal within a formative feedback system.

Harrison is an urban, culturally diverse K-8 school serving more than 500 students in a large Midwest city. Once identified as a “school in need of improvement” under the NCLB criteria, the Harrison staff applied for and received a Comprehensive School Reform grant to reorganize the school around the Direct Instruction curriculum. DDIS researcher Chris Thomas’ dissertation (2007) chronicled the story of the Harrison’s implementation of the Direct Instruction. The Harrison staff initially chose DI in the 1999 school year because the existing instructional program seemed to be a program in name only. To the incoming Harrison principal, it seemed as though “everybody was doing their own thing...the former principal was not aware of a specific reading program...and our reading resource teacher wasn’t aware of a specific program either.” The district played an interesting role in Harrison’s selection of DI. In the early 2000s, the district approach to the school instructional program was to recommend the acceptance of common, district-wide learning outcomes, and leave the selection of the means toward those outcomes to the local schools. The DI approach, in contrast, was to tightly link instructional means and outcomes and to remove local discretion from the instructional process. Further, there were significant differences between the district learning goals and the DI learning outcomes. Still, there were enough schools in Harrison’s large urban district using DI that the district grudgingly recognized the DI schools and provided limited funding for district-level DI support.

The primary focus of the Harrison implementation of DI was for literacy in the early grades. The structured DI instructional program generated information about

student learning in terms of a common curriculum and common learning standards. The common approach to instruction allowed Harrison teachers to develop a shared vocabulary about instruction, and to discuss student learning in terms of a common curricular reference point. The shared curriculum enabled the DI staff to play a collaborative role with teachers in analyzing the considerable amount of data produced in a typical DI classroom. The signal produced by the DI instructional initiative was comprised of the performances of student learning that could be captured by the DI assessment system. In DI, the signal was coordinated due to the planned nature of the tasks engaged in by teachers throughout the school and across grade levels. These coordinated tasks allowed for the DI assessment to capture a coherent signal regarding student learning (in terms of the goals of the DI curriculum). Comparing the signal generated by the DI intervention enabled staff to identify which topics students were learning. Measuring the DI signal with other kinds of assessments, such as DiBELS¹ and Six Traits Writing², enabled the Harrison staff to determine the degree to which the DI instructional program needed to be supplemented with other curricula. DI thus provided the foundation for a common approach to instruction, and the Harrison were able to use the narrow range of the DI curriculum signal as an opportunity for the staff to determine which programs were needed to supplement the DI program.

The Pearson Balanced Literacy program provided a different approach to intervention assembly. The Pearson Elementary School is a small-town K-6 school of

¹ DiBELS, or Dynamic Indicators of Basic Early Literacy Skills, are a set of standardized, individually administered measures of early literacy development. They are designed to be short (one minute) fluency measures used to regularly monitor the development of pre-reading and early reading skills (<http://dibels.uoregon.edu/>).

² Six Traits of Writing is a comprehensive intervention developed by the Northwest Regional Education Laboratory (NWREL) that organizes the writing process in terms of ideas, organization, voice, sentence fluency and word choice (<http://www.nwrel.org/assessment/department.php?d=1>)

300 students. The leaders and teachers at Pearson Elementary School organized a formative feedback system around early literacy instruction. Over the past eight years, the Pearson principal and her teachers built structures that allow teachers to focus on particular learning problems, such as the development of early literacy skills, that limited student learning gains across the curriculum. In terms of our formative feedback system model, the reading curriculum was the *intervention*, a battery of commercial exams used by Pearson teachers was the *assessment*, and the regular grade level meetings for teacher reflection and action was the *actuation space*.

The Pearson Balanced Literacy program is an example of a locally designed instructional intervention. This package of curricula was stitched together under the guidance of the Pearson principal and Title 1 teacher. The impetus for the Pearson literacy program was a district (and state) press to improve the quality of K-2 reading teaching for all students. The building blocks for the Pearson Balanced Literacy program are Guided Reading, Reading Recovery and Orton-Gillingham phonics. The Literacy Coordinator stated that the Guided Reading program “is our Bible.” Guided Reading teachers helped small groups of students use the contextual and visual cues in a book to understand the meaning of stories. Guided Reading leads students through a series of texts organized according to demonstrated reading levels. Student grouping is determined by a series of quick assessments, or running records, that each teacher is expected to conduct to track student progress.

The Literacy Coordinator was trained as a Reading Recovery (RR) teacher, but found RR too expensive and intensive to serve the needs of all students at Pearson. RR was also provided by pulling students out of their classrooms, which meant that, “a child

could have a different classroom teacher, reading teacher, and Reading Recovery teacher.” She found the Guided Reading program to be “an absolutely excellent” alternative to RR for teaching reading, and helped the K-2 teachers adapt some of the RR writing materials into the literacy program. Guided Reading, though, proved difficult to implement with new readers who struggled with simple phonics skills. All Pearson reading teachers have attended workshops on the Orton-Gillingham approach to phonics teaching. Orton-Gillingham involves daily practice in sounds and word decoding skills to prepare students for book reading. The guided reading sessions could then be used as diagnostic sessions to identify the kinds of phonics skills students were missing. The common staff training and commitment to Guided Reading and Orton-Gillingham helped provide program focus for students so that, in Wagner’s view “now the language is common, and even our struggling readers understand what we are talking about.” Teachers at Pearson credited the effective use of data for much of their success with improving student achievement. As one teacher put it succinctly: “We use the data ourselves to see student growth.”

The role of an intervention in a formative feedback system is to transmit a clear signal about student learning that can be measured through assessments and acted upon in actuality. In practice, the focus on producing an actionable signal to indicate student learning meant that the Pearson staff needed to standardize and streamline the patchwork curricular intervention in order to produce a clear signal. The need to coordinate interventions to produce a clear signal had important implications for school program design. Leaders and teachers at Harrison and Pearson had to collaboratively agree to standardize teaching across the grade level by coordinating the content and

spacing of their instruction. If teachers would select their own curricular activities, or if they would decide on their own spacing, then it would be difficult to ascertain a clear signal that could be readily compared across classrooms or grades to report student learning progress. The coordination of the instructional program, in fact, led us to define intervention coordination as a boundary definition for whether the school had developed a formative feedback system in a given instructional area.

The difference between adopting received or locally designed intervention artifacts led to distinctive, but ultimately convergent, formative feedback system challenges. At Harrison, the decision to adopt Direct Instruction required teachers to commit to common topic selection and a shared spacing schedule. As a result, the literacy intervention produced a clear signal about student learning. However, the challenge with Direct Instruction was to determine the *adequacy* of the signal as an indicator of student learning. The state test score results showed that the Direct Instruction curriculum led to student learning gains in certain domains, but it left gaps in student performance in other areas (for example, reading comprehension in the upper grades, and writing). In other words, comparing the DI signal with the state test score results called into question the adequacy of the intervention signal to indicate student learning, and the formative feedback system led to intervention supplements that bolstered the signal adequacy. The locally designed intervention at Pearson faced a different challenge – signal *coherence*. Each component of the Balanced Literacy program (phonics, Guided Reading, Reading Recovery) produced a distinct learning signal. Ultimately, the relation between signal coherence and adequacy forms an on-going design refinement in a formative feedback system. At Harrison, the addition of supplemental programs to address signal adequacy

issues raised the problem of how the programs fit together as a signal coherence issue, and after building the Balanced Literacy program, Pearson staff had to compare the resulting signal with the independent state test results to again gauge signal adequacy. Thus the establishment of a clear intervention signal can be seen as both a condition for and an on-going process within a vibrant formative feedback system.

Assessments

The role of an assessment in a formative feedback system is to sense the signal sent by the intervention in a way that facilitates corrective action by school staff. A formative feedback system assessment translates the intervention signal into a format that helps to create a shared understanding of what the signal means among staff. Schools are typically awash in many different types of assessment data, and it is a significant design challenge to constrain the various assessments to produce a reliable and shared measure of student learning. School learning assessments exist at many different levels and serve different purposes. Schools and districts are held accountable by government for documenting student learning in terms of summative standardized tests. Local schools and classrooms receive and design a wide variety of formative assessments, ranging from benchmark assessment systems, to teacher developed quizzes and homework checks, to monitor the learning process. A challenge of formative feedback system design is to establish a direct link between interventions and assessments in order to create actionable information for faculty and staff.

Benchmark assessment systems have recently emerged as tools that schools develop or purchase to provide timely and appropriate data to guide schools in making effective decisions about teaching and learning (This issue, Burch, Marion, et. al.).

Benchmark assessment systems require students to undergo intermittent standards-guided testing, often through computer-adaptive testing, to provide interim achievement information about students' progress through the school instructional program. The systems typically involve output processes to deliver the assessment information in student-level or learning standard level reports that make sense for guiding teaching and learning. Benchmark assessment systems, such as MAP or McGraw-Hill's *Acuity*, are typically district wide assessment products that aim to provide on-going information on student progress toward learning goals. Some benchmark systems are computer adaptive tests that narrow the range of appropriate items offered to individual test-takers based on responses to prior items (Cronin, 2004). Items are selected according to the match with state or local standards in math, literacy and science.³ Benchmark systems such as MAP also address the time-lag involved in standardized testing – results from MAP are typically available to schools in less than 3 days. Finally, MAP provides several reporting tools designed to convey the results of testing in terms teachers can act upon, and curriculum tools to point teachers toward viable course of instructional action.

The Walker school experience with implementing the MAP benchmark assessment system provides a good example of the design challenges involved in creating assessments in a formative feedback system. Walker is a rural grade 3-5 school with an enrollment of about 400 students. About 90% of the Walker students score proficient or advanced on the state test. Reid Pritchett's dissertation work (2007) related the story of how the Walker school leaders and teachers worked to create a local formative feedback system by articulating the connection between the school interventions and the MAP

³ See xxxxx, (this issue) for a consideration of how items are selected to reflect core standards in Philadelphia

system. In 2004, the Walker district decided to purchase the Northwest Education Association's Measures of Academic Progress (MAP) benchmark assessment system, and the district curriculum director worked with Walker teachers to integrate MAP into the instructional program. The Walker teachers had already developed a basic formative feedback system (similar to the Pearson school model) in literacy and language arts, and took the implementation of MAP as an opportunity to coordinate the math instructional program. For Walker school, the math curriculum was the intervention, the MAP benchmark assessment system was the assessment, and the regular meetings of the math department provided the actuation space for the formative feedback system.

The Walker implementation of MAP was initiated by district leaders eager to acquire the capacity for system-wide, intermittent measures of student learning. The district curriculum director perceived that the state test did not generate sufficiently actionable information, and, by 2003, "(we) didn't have an assessment tool where we could get information quickly about reading, writing, and math. And we needed not only for something to be easily administered, but also get the information quickly back." In 2004, the district developed a committee of leaders and teachers who decided to purchase and implement MAP in grades 3-8. The committee felt confident that MAP would provide the kinds of information district leaders thought teachers would need to make adjustments in instructional practices. In 2004-2005, the district purchased MAP and helped district schools coordinate the professional development sessions necessary to help teachers integrate MAP data into their classes.

The Walker school principal clearly saw the possibilities of MAP for classroom formative feedback. She thought that MAP would help teachers to measure students in

terms of local standards, to “give (teachers) a kind of a foundation ... a consistent way of analyzing where a student might fall within expectations, either by the state or their national norms, and then how that aligns with what they’re doing in the classroom.” Further, MAP would provide a context to that would provide “a consistent way of assessing a child and then to reflect on how consistent that is with what they’re seeing in their individual classrooms.” The Walker teachers, however, were hesitant about the possibility of MAP being used as a teacher evaluation tool. One teacher commented that MAP data could add to whether “they decide they want to get rid of you, that’s one thing that they could use against you.” Over time, teacher concerns about teacher evaluation eased as the principal helped teachers make sense of the MAP data reports. She used MAP reports as a justification for actuation spaces that afforded extended conversations with each teacher about learning with each student in their classrooms. These conversations helped teachers to see how the MAP data could be used to guide instructional improvement. Further, the Walker principal used MAP data in faculty and staff meetings to create a common vocabulary for Walker teachers to discuss student learning. After the second year of MAP implementation, one teacher noted that MAP provided an “extra set of eyes to confirm that you’re doing something well or that you need to do something different.”

The experience of implementing MAP at the Walker school reflected a tension between purchased benchmark assessment systems and a functional, school-wide formative assessment system. Walker’s initial implementation of MAP focused on how teachers could individually use MAP data to improve learning. After 3 years, 80% of teachers reported using MAP data to group students in their own classrooms, but only

30% reported using MAP to evaluate the effectiveness of the instructional program. In a school-wide formative feedback system, leaders and teachers use information to make adjustments not for individual students, but also to the interventions themselves.

Beginning in the third year of implementation, Walker teachers were beginning to create linkages between MAP data and the school interventions. In math, for example, a team of teachers from across grade levels painstakingly analyzed district geometry curricula to determine just where the MAP assessments of student learning could be used to guide classroom instruction.

The Walker school implementation of MAP illustrates some of the issues that arise in the assembly of a formative feedback system. Formative feedback systems depend on the ability of the assessment sensor to interpret the intervention signal in a format that supports teacher action. If the MAP assessment and the curriculum are both aligned with state standards, then one might assume that the assessment and the intervention are aligned as well. The Walker experience suggests that the alignment of signal and sensor alone will not produce actionable system-wide information. The key for understanding the difficulty of using MAP in a formative feedback system is that teachers teach lessons, not standards, and that MAP is aligned to standards, not lessons. Porter (1995) argued that unless there is a tight match between what is assessed and what is taught, the assessment results can be meaningless, and the resulting decisions are potentially harmful. If the measures of learning do not follow directly from instructional practices, teachers may have difficulty determining how to interpret the resulting signals in terms of teaching practices. The key assessment design issue in the formative assessment systems we observed might be described as creating an actionable fit between

intervention signal and the assessment sensor. Teachers who put the time into understanding the relation between, for example, the MAP lexile scores and reading comprehension lessons, will be able to use MAP data to guide instruction. Absent efforts to collaboratively build connections between interventions and assessments, benchmark assessment systems may simply reinforce the isolated expertise of teachers willing to create formative feedback from benchmark data.

Actuation

Creating a strong link between assessments and actuation spaces are one way that school leaders can influence practitioner sense-making so that teachers are able to act effectively on local practice in terms of the local policy context (Coburn, 2005). Each school provided examples of many actuation spaces such as grade-level and faculty meetings. However, only a few of these spaces appeared integrated into formative feedback systems. We identified three features that differentiated formative feedback actuation spaces from ordinary meetings. First, the agenda for the meetings were established as on-going conversations about assessment data. Second, staff included in the actuation meetings had persistent roles as active members of a formative assessment review team. Finally, team members felt authorized to use assessment data for taking action at both the student and the intervention level. School leaders played a key role in scheduling adequate time and resources for actuation spaces, negotiating agendas and the range of responsibilities with team members, and distributing authority so that the actuation teams were empowered to take the action deemed necessary. In our research, the actuation spaces provided good examples of the social distribution of leadership practice (Spillane, 2006).

The Malcolm School Respect and Responsibility (R&R) program provides an example of how leaders structured actuation space for a formative feedback system. Malcolm is an urban k-5 school with a highly mobile population of 220 children. In the past several years, 70% of Malcolm's students have qualified for free or reduced lunch. The school's proportion of minority students is among the highest in the district. Malcolm is a school-wide Title I school, and it is eligible for state class-size reduction funding. In spite of the challenging population, Malcolm had improved their student standardized test scores to the point that they now rival those of any other school in the district. Malcolm developed data driven support system for student behavior, the Respect and Responsibility Program (R&R), that addressed both program level and student level concerns at the school. The student service staff, including school psychologists, Title I teacher, special educators and social workers, facilitated these supports as well as play an integral role in making sense of data taken on program and student level interventions. For Malcolm school, a variety of interventions constituted the intervention, the student behavior information system was the Assessment, and the R&R, grade-level and faculty committees provided the actuation spaces for the formative feedback system.

Leaders at Malcolm felt that the learning issues of the predominantly low-income student population could best be addressed with a good curriculum and a safe learning environment. The Malcolm district provided nationally renowned curricular initiatives in reading and math that included common lesson design across classrooms, benchmark subject area assessments, and guidelines for faculty collaboration and action. Beginning in 2002, Malcolm school leaders decided to focus their efforts to locally design a program to monitor and manage student behavior in order to create a safe learning

environment. The school develop R&R from a number of traditional policies and programs intended to help students develop conflict management strategies and to guide teachers in addressing behavioral issues in the classroom. R&R data were gathered through multiple reporting tools and compiled in a networked spreadsheet that records incidents reported on a standard form including the nature of the incident, the time and location, and the prior interventions attempted.

The R&R actuation space involved a sequence of professional meetings through which the spreadsheet data are analyzed, reported, and made actionable in terms of teacher practice. The spreadsheet was reviewed weekly by the R&R committee, a team of non-teaching staff who monitored and reflected upon the student behavioral data in the hope of identifying emergent systemic issues within the school. Some of these issues are strictly practical, such as the high frequency of referrals as students return from the playground, whereas others concern equity, such as the frequency of incidents for African-American boys. The R&R committee compiles a monthly report that is shared with the Malcolm staff in grade level meetings. The meetings with faculty address questions such as the persistence of data across years, the overall percentage of students who are referred, the distribution of referrals by grade, and referral trends for individual students. One member of the R&R team offered an example of how their data review process led to an intervention on behalf of a teacher: “We helped the teacher to change the layout- the physical plans, where the desks were, where the work space was and got rid of a lot of clutter. Then the referrals went down.” The principal appeared at each grade-level meeting to share the data with them and to identify any patterns—positive or

negative—that may arise. As the principal noted, the more frequent review of the data has allowed them to be “much more aggressive with interventions.”

Malcolm leaders provided another level of actuation space for acute student concerns, the Building Consultation Team (BCT). A Building Consultation Team is convened to address issues pertaining to a particular student. Similar to the special education Individualized Education Plan process, a BCT committee convenes to address behavioral issues for individual students. Rather, the BCT serves to provide interventions for a portion of the student population for whom it is deemed necessary. Like an IEP, the BCT includes staff members who interact with students in a number of different contexts, including the classroom teacher, support staff, and school administrators; parents are always invited to the meetings and frequently attend them. Some students ultimately end up being referred for an IEP, but many do not. Sharing and responding to the data provides a purpose for its collection and, in the case of this school, leads to increased demand for it. As a district administrator commented, “You have got to use data. I mean, you’re not just creating data to create data, you have to create it for a purpose,” and the school’s principal told her staff, “The beauty of data is that we can have these conversations.”

The R&R actuation spaces illustrate several key features of formative feedback systems. First, the actuation spaces legitimate a school-wide *sense making* process. Sense-making reflects individual and group efforts to notice or interpret new stimuli in light of prior knowledge, belief and experience. (Spillane, Reiser & Reimer, 2002). Actuation spaces create contexts in which staff can engage in collective sense-making in order to make decisions about teaching and learning. The school’s principal once

remarked to her staff that, “There’s not one secret with data in this building.” The R&R actuation spaces scaffold the sense-making process for Malcolm staff. The R&R committee sifted through behavior reporting system data to discern teacher and student patterns. Rather than hold staff accountable for these findings, the next phase of actuation space – grade-level meetings – are structured to provide opportunities for teachers to reflect on what the behavioral data reports mean in terms of teacher practice.

Transforming faculty meeting times into structured sense-making spaces legitimates the data collection process, and creates an expectation that data review sessions are a necessary aspect of professional practice at Malcolm.

Second, the actuation spaces enable teachers to alter interventions for individual students, within classrooms, or school-wide. The link between actuation spaces and intervention represents the *controller* function in the formative feedback system. The controller function allows the system to act appropriately on the feedback information. In the case of a school formative feedback system, the controller function enables practitioners to adjust the instructional program. The BCT sessions often follow directly from the R&R meetings to build a learning or behavioral plan for an individual student. The grade-level meetings encourage teachers to discuss changes in classroom practices. The Malcolm actuation spaces also create the perceived need for alteration or design of school-wide interventions. For example, in 2005-06, the erosion of student behavior led Malcolm staff to design a series of academic parent-community nights designed to improve family understanding of district curricular programs. The staff felt that if parents could work with students to improve academic performance, students would be less frustrated in school and more willing to engage in classroom lessons. This critical

function of actuation spaces reinforces the legitimacy of the entire formative feedback system. If teachers and staff generate, record, and analyze data in order to develop or refine existing interventions, only to be reminded that they do not have the power to alter the instructional program, subsequent cycles of the feedback system are much less likely to be formative. We found that the dense interaction around behavioral data at Malcolm (as with literacy data at Pearson and Harrison) contributed to a vibrant professional community in which teachers felt comfortable making their classroom practice public. The sustained success of a formative feedback system in a loosely coupled school system appears, at least in part, to rest on the belief that the actions taken as a result of the data will count in shaping future practice.

Conclusion

Formative feedback systems are an important aspect of data-driven instructional capacity in schools. A systems theory approach enabled the analysis of school data practices around the language of signals, sensors, processors and actuation. This paper described how formative feedback systems are composed of links between interventions, assessments and actuation spaces that enable school staff to act upon student learning information. A formative feedback system model can thus be seen as a kind of organizational capacity designed to develop and distribute information about the instructional program. Seen in this light, a formative feedback system provides a generic description of the capacity that tools such as comprehensive school reforms, benchmark assessment systems or student behavior management programs seek to cultivate in schools. Such interventions rely on the development of interventions, assessments and

actuation spaces, and on the designed interaction among these components, to act as effective formative feedback systems.

The argument was designed to make a modest claim about data-driven instructional practices. Neither the concept nor the programs identified as components of formative feedback systems are new. Thousands of schools use phonics, Guided Reading, running records, faculty meetings and behavior management programs to conduct their business. The cases presented from the DDIS study illustrate how school data practices might be analyzed collectively as the result of design in terms of formative feedback system functions. School leaders and teachers in the DDIS schools used humble components to construct powerful formative feedback systems that provide sophisticated, carefully selected information that enable schools to customize their instructional programs on the fly. Describing a model that captures these designed feedback loops of instruction, assessment, and actuation may lead researchers to document these practices so that others can understand how to organize feedback systems in their schools. In the 1990s, businesses and schools around the world went in search of the elusive learning organizations. In the 2000s, we find local leaders and teachers constructing the building blocks of genuine learning organizations in early literacy programs. Perhaps the key to making these practices accessible to all schools begins with the simple step of providing a common vocabulary and framework to communicate this new form of instructional leadership.
